

An Implementation of Sin and Cos Using Gal's Accurate Tables

Pascal Leroy (phl)

2025-02-02

This document describes the implementation of functions Sin and Cos in Principia. The goals of that implementation are to be portable (including to machines that do not have a fused multiply-add instruction), achieve good performance, and ensure correct rounding.

Overview

The implementation follows the ideas described by [GB91] and uses accurate tables produced by the method presented in [SZ05]. It guarantees correct rounding with a high probability. In circumstances where it cannot guarantee correct rounding, it falls back to the (slower but correct) implementation provided by the CORE-MATH project [SZG22] [ZSG+24]. More precisely, the algorithm proceeds through the following steps:

- perform argument reduction using Cody and Waite's algorithm in double precision (see [Mul+10, p. 379]);
- if argument reduction loses too many bits (i.e., the argument is close to a multiple of $\frac{\pi}{2}$), fall back to `cr_sin` or `cr_cos`;
- otherwise, uses accurate tables and a polynomial approximation to compute Sin or Cos with extra accuracy;
- if the result has a “dangerous rounding configuration” (as defined by [GB91]), fall back to `cr_sin` or `cr_cos`;
- otherwise return the rounded result of the preceding computation.

In this document we assume a base-2 floating-point number system with M significand bits¹ similar to the IEEE formats. We define a real function `m` and an integer function `e` denoting the *significand* and *exponent* of a real number, respectively:

$$x = \pm m(x) \times 2^{e(x)} \quad \text{with} \quad 2^{M-1} \leq m(x) \leq 2^M - 1$$

Note that this representation is unique. Furthermore, if x is a floating-point number, `m(x)` is an integer.

The distance between 1 and the next larger floating-point number is:

$$\epsilon_M := 2^{1-M}$$

and the distance between 1 and the next smaller floating-point number is $\frac{\epsilon_M}{2}$. The *unit of the last place* of x is defined as:

$$u(x) := 2^{e(x)}$$

In particular, $u(1) = \epsilon_M$.

We ignore the exponent bias, overflow and underflow as they play no role in this discussion.

Finally, for error analysis we use the accuracy model of [Higo2], equation (2.4): unless otherwise indicated, δ_i is a roundoff factor such that $\delta_i < u = \epsilon_M/2 = 2^{-M}$ (see pages 37 and 38). We also use θ_n and γ_n with the same meaning as in [Higo2], lemma 3.1.

¹In binary64, $M = 53$.

Approximation of $\frac{\pi}{2}$

To perform argument reduction, we need to build approximations of $\frac{\pi}{2}$ with extra accuracy and analyse the circumstances under which they may be used and the errors that they entail on the reduced argument.

We start by defining the truncation function $\text{Tr}(\kappa, z)$ which clears the last κ bits of the mantissa of z :

$$\text{Tr}(\kappa, z) := \lfloor 2^{-\kappa} m(z) \rfloor 2^\kappa u(z)$$

The definition of the floor function implies:

$$0 \leq z - \text{Tr}(\kappa, z) < 2^\kappa u(z)$$

Furthermore if the bits that are being truncated start with k zeros we have the stricter inequality:

$$0 \leq z - \text{Tr}(\kappa, z) < 2^{\kappa'} u(z) \quad \text{with} \quad \kappa' = \kappa - k$$

This leads to the following upper bound for the unit of the last place of the truncation error:

$$u(z - \text{Tr}(\kappa, z)) < \frac{2^{\kappa'} u(z)}{m(z - \text{Tr}(\kappa, z))} \leq 2^{\kappa' - M + 1} u(z)$$

which can be made more precise by noting that the function u is always a power of 2:

$$u(z - \text{Tr}(\kappa, z)) = 2^{\kappa' - M} u(z) \quad (1)$$

Two-Term Approximation

In this scheme we approximate $\frac{\pi}{2}$ as the sum of two floating-point numbers:

$$\frac{\pi}{2} \simeq C_1 + \delta C_1$$

which are defined as:

$$\begin{cases} C_1 & := \text{Tr}\left(\kappa_1, \frac{\pi}{2}\right) \\ \delta C_1 & := \left\lfloor \frac{\pi}{2} - C_1 \right\rfloor \end{cases}$$

Equation (1) becomes:

$$u\left(\frac{\pi}{2} - C_1\right) = 2^{\kappa'_1 - M} u\left(\frac{\pi}{2}\right)$$

where $\kappa'_1 \leq \kappa_1$ accounts for any leading zeroes in the bits of $\frac{\pi}{2}$ that are being truncated. The absolute error on the two-term approximation is therefore:

$$\left| \frac{\pi}{2} - C_1 - \delta C_1 \right| \leq \frac{1}{2} u\left(\frac{\pi}{2} - C_1\right) = 2^{\kappa'_1 - M - 1} u\left(\frac{\pi}{2}\right) \quad (2)$$

In other words, we have a representation with a significand that has effectively $2M - \kappa'_1$ bits and is such that multiplying C_1 by an integer less than or equal to $2^{\kappa'_1}$ is exact.

Three-Term Approximation

In this scheme we approximate $\frac{\pi}{2}$ as the sum of three floating-point numbers:

$$\frac{\pi}{2} \simeq C_2 + C'_2 + \delta C_2$$

which are defined as:

$$\begin{cases} C_2 & := \text{Tr}\left(\kappa_2, \frac{\pi}{2}\right) \\ C'_2 & := \text{Tr}\left(\kappa_2, \frac{\pi}{2} - C_2\right) \\ \delta C_2 & := \left\lfloor \frac{\pi}{2} - C_2 - C'_2 \right\rfloor \end{cases}$$

Applying equation (1) to the definition of C_2 yields:

$$u\left(\frac{\pi}{2} - C_2\right) = 2^{\kappa'_2 - M} u\left(\frac{\pi}{2}\right)$$

where $\kappa'_2 \leq \kappa_2$ accounts for any leading zeroes in the bits of $\frac{\pi}{2}$ that are being truncated. Similarly, applying equation (1) to the definition of C'_2 yields:

$$\begin{aligned} u\left(\frac{\pi}{2} - C_2 - C'_2\right) &= 2^{\kappa''_2 - M} u\left(\frac{\pi}{2} - C_2\right) \\ &= 2^{\kappa'_2 + \kappa''_2 - 2M} u\left(\frac{\pi}{2}\right) \end{aligned}$$

where $\kappa''_2 \leq \kappa_2$ accounts for any leading zeroes in the bits of $\frac{\pi}{2} - C_2$ that are being truncated. Note that normalization of the mantissa of $\frac{\pi}{2} - C_2$ effectively drops the zeroes at positions κ_2 to κ'_2 and therefore the computation of C'_2 applies to a mantissa aligned on position κ'_2 .

Argument Reduction

Given an argument x , the purpose of argument reduction is to compute a pair of floating-point numbers $(\hat{x}, \delta\hat{x})$ such that:

$$\begin{cases} \hat{x} + \delta\hat{x} \cong x \pmod{\frac{\pi}{2}} \\ \hat{x} \text{ is approximately in } \left[-\frac{\pi}{4}, \frac{\pi}{4}\right] \\ |\delta\hat{x}| < u(\hat{x}) \end{cases}$$

Argument Reduction for Small Angles

If $|x| < \left\lfloor \frac{\pi}{4} \right\rfloor$ then $\hat{x} = x$ and $\delta\hat{x} = 0$.

Argument Reduction for Medium Angles

If $|x| \leq 2^{\kappa_1} \left\lfloor \frac{\pi}{2} \right\rfloor$ then we compute:

$$\begin{cases} n &= \left\lfloor \left\lfloor x \left\lfloor \frac{2}{\pi} \right\rfloor \right\rfloor \right\rfloor \\ y &= x - n C \\ \delta y &= \left\lfloor n \delta C \right\rfloor \\ \hat{x} &= \left\lfloor y - \delta y \right\rfloor \\ \delta\hat{x} &= (y - \hat{x}) - \delta y \end{cases}$$

Let's first show that $|n| \leq 2^{\kappa_1}$. :

$$\begin{aligned} |x| &\leq 2^{\kappa_1} \frac{\pi}{2} (1 + \delta_1) \\ |n| &\leq \left\lfloor 2^{\kappa_1} \frac{\pi}{2} (1 + \delta_1) \frac{2}{\pi} (1 + \delta_2) (1 + \delta_3) \right\rfloor \\ &\leq \lceil 2^{\kappa_1} (1 + \gamma_3) \rceil \end{aligned}$$

Because $2^{\kappa_1} \gamma_3$ is very small (less than 2^{-33}), the rounding cannot cause n to exceed 2^{κ_1} .

The product $n C$ is exact thanks to the κ_1 trailing zeroes of C . The subtraction $x - n C$ is exact by Sterbenz's Lemma. Finally, the last two steps form a compensated summation so that $\hat{x} + \delta\hat{x} = y + \delta y$.

To compute the overall error on argument reduction, first remember that, from equation 2 we have:

$$C + \delta C = \frac{\pi}{2} + \delta_5 \quad \text{with} \quad |\delta_5| \leq 2^{\kappa_2 - M - 1} u\left(\frac{\pi}{2}\right)$$

The error computation proceeds as follows:

$$\begin{aligned} y + \delta y &= x - n C - n \delta C (1 + \delta_4) \\ &= x - n(C + \delta C) - n \delta C \delta_4 \\ &= x - n \frac{\pi}{2} - n(\delta_5 + \delta C \delta_4) \end{aligned}$$

from which we can deduce an upper bound on the absolute error:

$$\left| y + \delta y - \left(x - n \frac{\pi}{2} \right) \right| < 2^{\kappa_1} 2^{\kappa_2} u \left(\frac{\pi}{2} \right) (2^{-M-1} + 2^{-M}) = \frac{3}{2} 2^{\kappa_1 + \kappa_2 - M} u \left(\frac{\pi}{2} \right)$$

where we have used the upper bound for δC given by equation ??.

Argument Reduction for Large Angles

Accurate Tables and Their Generation

Computation of the Functions

Sin

Near Zero

For \hat{x} near zero we evaluate:

$$\begin{aligned} \widehat{x^2} &= \llbracket \hat{x}^2 \rrbracket = \hat{x}^2 (1 + \delta_1) \\ \widehat{x^3} &= \llbracket \hat{x} \widehat{x^2} \rrbracket = \hat{x}^3 (1 + \delta_1) (1 + \delta_2) \\ \hat{p} &= \llbracket a \widehat{x^2} + b \rrbracket = (a \hat{x}^2 (1 + \delta_1) + b) (1 + \delta_3) \\ s(x) &:= \hat{x} + \llbracket \llbracket \widehat{x^3} \hat{p} \rrbracket + \delta \hat{x} \rrbracket \\ &= \hat{x} + (\hat{x}^3 (1 + \delta_1) (1 + \delta_2) (a \hat{x}^2 (1 + \delta_1) + b) (1 + \delta_3) (1 + \delta_4) + \delta \hat{x}) (1 + \delta_5) \\ &= \hat{x} + a \hat{x}^5 (1 + \theta_5) + b \hat{x}^5 (1 + \theta_4) + \delta \hat{x} (1 + \delta_5) \end{aligned}$$
