

An Implementation of Sin and Cos Using Gal's Accurate Tables

Pascal Leroy (phl)

2025-02-02

This document describes the implementation of functions `Sin` and `Cos` in Principia. The goals of that implementation are to be portable (including to machines that do not have a fused multiply-add instruction), achieve good performance, and ensure correct rounding.

Overview

The implementation follows the ideas described by [GB91] and uses accurate tables produced by the method presented in [SZ05]. It guarantees correct rounding with a high probability. In circumstances where it cannot guarantee correct rounding, it falls back to the (slower but correct) implementation provided by the CORE-MATH project [SZG22] [ZSG+24]. More precisely, the algorithm proceeds through the following steps:

- perform argument reduction using Cody and Waite's algorithm in double precision (see [Mul+10, p. 379]);
- if argument reduction loses too many bits (i.e., the argument is close to a multiple of $\frac{\pi}{2}$), fall back to `cr_sin` or `cr_cos`;
- otherwise, uses accurate tables and a polynomial approximation to compute `Sin` or `Cos` with extra accuracy;
- if the result has a “dangerous rounding configuration” (as defined by [GB91]), fall back to `cr_sin` or `cr_cos`;
- otherwise return the rounded result of the preceding computation.

Notation and Accuracy Model

In this document we assume a base-2 floating-point number system with M significand bits¹ similar to the IEEE formats. We define a real function m and an integer function e denoting the *significand* and *exponent* of a real number, respectively:

$$x = \pm m(x) \times 2^{e(x)} \quad \text{with} \quad 2^{M-1} \leq m(x) \leq 2^M - 1$$

Note that this representation is unique. Furthermore, if x is a floating-point number, $m(x)$ is an integer.

The distance between 1 and the next larger floating-point number is:

$$\epsilon_M := 2^{1-M}$$

and the distance between 1 and the next smaller floating-point number is $\frac{\epsilon_M}{2}$. The *unit of the last place* of x is defined as:

$$u(x) := 2^{e(x)}$$

In particular, $u(1) = \epsilon_M$ and:

$$\frac{x \epsilon_M}{2} < \frac{x}{2^M - 1} \leq u(x) \leq \frac{x}{2^{M-1}} = x \epsilon_M \quad (1)$$

¹In binary64, $M = 53$.

We ignore the exponent bias, overflow and underflow as they play no role in this discussion.

Finally, for error analysis we use the accuracy model of [Higo2], equation (2.4): everywhere they appear, the quantities δ_i represent a roundoff factor such that $\delta_i < u = \epsilon_M/2 = 2^{-M}$ (see pages 37 and 38). We also use θ_n and γ_n with the same meaning as in [Higo2], lemma 3.1.

Approximation of $\frac{\pi}{2}$

To perform argument reduction, we need to build approximations of $\frac{\pi}{2}$ with extra accuracy and analyse the circumstances under which they may be used and the errors that they entail on the reduced argument.

We start by defining the truncation function $\text{Tr}(\kappa, z)$ which clears the last κ bits of the significand of z :

$$\text{Tr}(\kappa, z) := \lfloor 2^{-\kappa} m(z) \rfloor 2^\kappa u(z)$$

The definition of the floor function implies:

$$0 \leq z - \text{Tr}(\kappa, z) < 2^\kappa u(z)$$

Furthermore if the bits that are being truncated start with exactly k zeros we have the stricter inequality:

$$2^{\kappa'-1} u(z) \leq z - \text{Tr}(\kappa, z) < 2^{\kappa'} u(z) \quad \text{with} \quad \kappa' = \kappa - k \quad (2)$$

This leads to the following upper bound for the unit of the last place of the truncation error:

$$u(z - \text{Tr}(\kappa, z)) < \frac{2^{\kappa'} u(z)}{m(z - \text{Tr}(\kappa, z))} \leq 2^{\kappa'-M+1} u(z)$$

which can be made more precise by noting that the function u is always a power of 2:

$$u(z - \text{Tr}(\kappa, z)) = 2^{\kappa'-M} u(z) \quad (3)$$

Two-Term Approximation

In this scheme we approximate $\frac{\pi}{2}$ as the sum of two floating-point numbers:

$$\frac{\pi}{2} \simeq C_1 + \delta C_1$$

which are defined as:

$$\begin{cases} C_1 &:= \text{Tr}\left(\kappa_1, \frac{\pi}{2}\right) \\ \delta C_1 &:= \left\lfloor \frac{\pi}{2} - C_1 \right\rfloor \end{cases}$$

Equation (2) applied to the definition of C_1 yields:

$$2^{\kappa'_1-1} u\left(\frac{\pi}{2}\right) \leq \frac{\pi}{2} - C_1 < 2^{\kappa'_1} u\left(\frac{\pi}{2}\right)$$

where $\kappa'_1 \leq \kappa_1$ accounts for any leading zeroes in the bits of $\frac{\pi}{2}$ that are being truncated. Accordingly equation (3) yields, for the unit of the last place:

$$u\left(\frac{\pi}{2} - C_1\right) = 2^{\kappa'_1-M} u\left(\frac{\pi}{2}\right)$$

Noting that the absolute error on the rounding that appears in the definition of δC_1 is bounded by $\frac{1}{2} u\left(\frac{\pi}{2} - C_1\right)$, we obtain the absolute error on the two-term approximation:

$$\left| \frac{\pi}{2} - C_1 - \delta C_1 \right| \leq \frac{1}{2} u\left(\frac{\pi}{2} - C_1\right) = 2^{\kappa'_1-M-1} u\left(\frac{\pi}{2}\right) \quad (4)$$

and the following upper bound for δC_1 :

$$|\delta C_1| < 2^{\kappa'_1} (1 + 2^{-M-1}) u\left(\frac{\pi}{2}\right) \quad (5)$$

This scheme gives a representation with a significand that has effectively $2M - \kappa'_1$ bits and is such that multiplying C_1 by an integer less than or equal to $2^{\kappa'_1}$ is exact.

Three-Term Approximation

In this scheme we approximate $\frac{\pi}{2}$ as the sum of three floating-point numbers:

$$\frac{\pi}{2} \simeq C_2 + C'_2 + \delta C_2$$

which are defined as:

$$\begin{cases} C_2 &:= \text{Tr}\left(\kappa_2, \frac{\pi}{2}\right) \\ C'_2 &:= \text{Tr}\left(\kappa'_2, \frac{\pi}{2} - C_2\right) \\ \delta C_2 &:= \left\llbracket \frac{\pi}{2} - C_2 - C'_2 \right\rrbracket \end{cases}$$

Equation (2) applied to the definition of C_2 yields:

$$2^{\kappa'_2-1} u\left(\frac{\pi}{2}\right) \leq \frac{\pi}{2} - C_2 < 2^{\kappa'_2} u\left(\frac{\pi}{2}\right) \quad (6)$$

where $\kappa'_2 \leq \kappa_2$ accounts for any leading zeroes in the bits of $\frac{\pi}{2}$ that are being truncated. Accordingly equation (3) yields, for the unit of the last place:

$$u\left(\frac{\pi}{2} - C_2\right) = 2^{\kappa'_2-M} u\left(\frac{\pi}{2}\right)$$

Similarly, equation (2) applied to the definition of C'_2 yields:

$$\begin{aligned} 2^{\kappa''_2-1} u\left(\frac{\pi}{2} - C_2\right) &\leq \frac{\pi}{2} - C_2 - C'_2 < 2^{\kappa''_2} u\left(\frac{\pi}{2} - C_2\right) \\ 2^{\kappa'_2+\kappa''_2-M-1} u\left(\frac{\pi}{2}\right) &\leq < 2^{\kappa'_2+\kappa''_2-M} u\left(\frac{\pi}{2}\right) \end{aligned}$$

where $\kappa''_2 \leq \kappa_2$ accounts for any leading zeroes in the bits of $\frac{\pi}{2} - C_2$ that are being truncated. Note that normalization of the significand of $\frac{\pi}{2} - C_2$ effectively drops the zeroes at positions κ_2 to κ'_2 and therefore the computation of C'_2 applies to a significand aligned on position κ'_2 .

It is straightforward to transform these inequalities using (6) to obtain bounds on C'_2 :

$$2^{\kappa'_2} \left(\frac{1}{2} - 2^{\kappa''_2-M}\right) u\left(\frac{\pi}{2}\right) < C'_2 < 2^{\kappa'_2} (1 - 2^{\kappa''_2-M-1}) u\left(\frac{\pi}{2}\right)$$

Equation (3) applied to the definition of C'_2 yields, for the unit of the last place:

$$\begin{aligned} u\left(\frac{\pi}{2} - C_2 - C'_2\right) &= 2^{\kappa''_2-M} u\left(\frac{\pi}{2} - C_2\right) \\ &= 2^{\kappa'_2+\kappa''_2-2M} u\left(\frac{\pi}{2}\right) \end{aligned}$$

Noting that the absolute error on the rounding that appears in the definition of δC_2 is bounded by $\frac{1}{2} u\left(\frac{\pi}{2} - C_2 - C'_2\right)$, we obtain the absolute error on the three-term approximation:

$$\left| \frac{\pi}{2} - C_2 - C'_2 - \delta C_2 \right| \leq \frac{1}{2} u\left(\frac{\pi}{2} - C_2 - C'_2\right) = 2^{\kappa'_2+\kappa''_2-2M-1} u\left(\frac{\pi}{2}\right) \quad (7)$$

and the following upper bound for δC_2 :

$$|\delta C_2| < 2^{\kappa'_2+\kappa''_2-M} (1 + 2^{-M-1}) u\left(\frac{\pi}{2}\right) \quad (8)$$

This scheme gives a representation with a significand that has effectively $3M - \kappa'_2 - \kappa''_2$ bits and is such that multiplying C_2 and C'_2 by an integer less than or equal to 2^{κ_2} is exact.

Argument Reduction

Given an argument x , the purpose of argument reduction is to compute a pair of floating-point numbers $(\hat{x}, \delta\hat{x})$ such that:

$$\begin{cases} \hat{x} + \delta\hat{x} \cong x \pmod{\frac{\pi}{2}} \\ \hat{x} \text{ is approximately in } \left[-\frac{\pi}{4}, \frac{\pi}{4}\right] \\ |\delta\hat{x}| \leq \frac{1}{2} u(\hat{x}) \end{cases}$$

Argument Reduction for Small Angles

If $|x| < \left\llbracket \frac{\pi}{4} \right\rrbracket$ then $\hat{x} = x$ and $\delta\hat{x} = 0$.

Argument Reduction Using the Two-Term Approximation

If $|x| \leq 2^{\kappa_1} \left\llbracket \frac{\pi}{2} \right\rrbracket$ we compute:

$$\begin{cases} n &= \left\llbracket \left\llbracket x \left\llbracket \frac{2}{\pi} \right\rrbracket \right\rrbracket \right\rrbracket \\ y &= x - n C_1 \\ \delta y &= \left\llbracket n \delta C_1 \right\rrbracket \\ (\hat{x}, \delta\hat{x}) &= \text{TwoDifference}(y, \delta y) \end{cases}$$

Let's first show that $|n| \leq 2^{\kappa_1}$. :

$$\begin{aligned} |x| &\leq 2^{\kappa_1} \frac{\pi}{2} (1 + \delta_1) \\ |n| &\leq \left\lceil 2^{\kappa_1} \frac{\pi}{2} (1 + \delta_1) \frac{2}{\pi} (1 + \delta_2) (1 + \delta_3) \right\rceil \\ &\leq \lceil 2^{\kappa_1} (1 + \gamma_3) \rceil \end{aligned}$$

As long as $2^{\kappa_1} \gamma_3$ is small enough (less than $1/2$), the rounding cannot cause n to exceed 2^{κ_1} . In practice we choose a relatively small value for κ_1 , so this condition is met.

The product $n C_1$ is exact thanks to the κ_1 trailing zeroes of C_1 . The subtraction $x - n C_1$ is exact by Sterbenz's Lemma. Finally, the last step performs an exact addition² using algorithm 4 of [HLBo8].

To compute the overall error on argument reduction, first remember that, from equation (4) we have:

$$C_1 + \delta C_1 = \frac{\pi}{2} + \zeta \quad \text{with} \quad |\zeta| \leq 2^{\kappa'_1 - M - 1} u\left(\frac{\pi}{2}\right)$$

²The more efficient *QuickTwoDifference* is not usable here. First, note that $|y|$ is an integral multiple of $u(x)$ and therefore, when not zero, may be as small as $u(x)$. Ignoring rounding errors we have:

$$|\delta y| \geq n 2^{\kappa'_1 - 1} u\left(\frac{\pi}{2}\right) \geq 2^{\kappa'_1 + M - 2} u\left(\frac{\pi}{2}\right) u(n)$$

where we used the bound given by equation (1). Now the computation of n can result in a value that is either in the same binade or in the binade below that of x . Therefore $u(n) \geq \frac{1}{2} u(x)$ and the above inequality becomes:

$$|\delta y| \geq 2^{\kappa'_1 + M - 3} u\left(\frac{\pi}{2}\right) u(x)$$

plugging $u\left(\frac{\pi}{2}\right) = 2^{1-M}$ we find:

$$|\delta y| \geq 2^{\kappa'_1 - 2} u(x)$$

Therefore, as long as $\kappa'_1 > 2$, there exist arguments x for which $|\delta y| > |y|$.

The error computation proceeds as follows:

$$\begin{aligned}
y - \delta y &= x - n C_1 - n \delta C_1 (1 + \delta_4) \\
&= x - n(C_1 + \delta C_1) - n \delta C_1 \delta_4 \\
&= x - n \frac{\pi}{2} - n(\zeta + \delta C_1 \delta_4)
\end{aligned}$$

from which we deduce an upper bound on the absolute error of the reduction:

$$\begin{aligned}
\left| y - \delta y - \left(x - n \frac{\pi}{2} \right) \right| &\leq 2^{\kappa_1} 2^{\kappa'_1} (2^{-M-1} + 2^{-M} + 2^{-2M-1}) u\left(\frac{\pi}{2}\right) \\
&= 2^{\kappa_1 + \kappa'_1 - M} \left(\frac{3}{2} + 2^{-M-1} \right) u\left(\frac{\pi}{2}\right) \\
&< 2^{\kappa_1 + \kappa'_1 - M + 1} u\left(\frac{\pi}{2}\right)
\end{aligned}$$

where we have used the upper bound for δC_1 given by equation (5).

If we want $\hat{x} + \delta \hat{x}$ to have κ_3 extra bits of accuracy, we must have:

$$2^{\kappa_1 + \kappa'_1 - M + 1} u\left(\frac{\pi}{2}\right) \leq 2^{-\kappa_3} |u(\hat{x})| \leq 2^{-\kappa_3 - M + 1} |\hat{x}|$$

which leads to the following condition on the reduced angle:

$$|\hat{x}| \geq 2^{\kappa_1 + \kappa'_1 + \kappa_3} u\left(\frac{\pi}{2}\right)$$

The rest of the implementation assumes that $\kappa_3 = 18$ to achieve correct rounding most of the time and detect cases of dangerous rounding. If we choose $\kappa_1 = 8$ we find that $\kappa'_1 = 5$ (because there are three consecutive zeroes at this location in the significand of $\frac{\pi}{2}$) and the desired accuracy is obtained as long as $|\hat{x}| \geq 2^{-21} \simeq 4.8 \times 10^{-7}$.

Argument Reduction Using the Three-Term Approximation

If $|x| \leq 2^{\kappa_2} \left\lfloor \frac{\pi}{2} \right\rfloor$ we compute:

$$\begin{cases}
n &= \left\lfloor \left\lfloor x \left\lfloor \frac{2}{\pi} \right\rfloor \right\rfloor \right\rfloor \\
y &= x - n C_2 \\
y' &= n C'_2 \\
\delta y &= \llbracket n \delta C_2 \rrbracket \\
(z, \delta z) &= \text{QuickTwoSum}(y', \delta y) \\
(\hat{x}, \delta \hat{x}) &= \text{LongSub}(y, (z, \delta z))
\end{cases}$$

where *LongSub* is the obvious modification of the algorithm *LongAdd* presented in section 5 of [Lin81]. Note that *QuickTwoSum* is usable for the computation of $(z, \delta z)$ because clearly $|\delta z| < |z|$.

It is straightforward to show, like we did in the preceding section, that:

$$|n| \leq \lceil 2^{\kappa_2} (1 + \gamma_3) \rceil$$

and therefore that $|n| \leq 2^{\kappa_2}$ as long as $2^{\kappa_2} \gamma_3 < 1/2$.

The products $n C_2$ and $n C'_2$ are exact thanks to the κ_2 trailing zeroes of C_2 and C'_2 . The subtraction $x - n C_2$ is exact by Sterbenz's Lemma.

Accurate Tables and Their Generation

Computation of the Functions

Sin

Near Zero

For \hat{x} near zero we evaluate:

$$\begin{aligned}
 \widehat{x^2} &= \llbracket \hat{x}^2 \rrbracket = \hat{x}^2(1 + \delta_1) \\
 \widehat{x^3} &= \llbracket \hat{x} \widehat{x^2} \rrbracket = \hat{x}^3(1 + \delta_1)(1 + \delta_2) \\
 \hat{p} &= \llbracket a\widehat{x^2} + b \rrbracket = (a\hat{x}^2(1 + \delta_1) + b)(1 + \delta_3) \\
 s(x) &:= \hat{x} + \llbracket \llbracket \widehat{x^3} \hat{p} \rrbracket + \delta \hat{x} \rrbracket \\
 &= \hat{x} + (\hat{x}^3(1 + \delta_1)(1 + \delta_2)(a\hat{x}^2(1 + \delta_1) + b)(1 + \delta_3)(1 + \delta_4) + \delta \hat{x})(1 + \delta_5) \\
 &= \hat{x} + a\hat{x}^5(1 + \theta_5) + b\hat{x}^5(1 + \theta_4) + \delta \hat{x}(1 + \delta_5)
 \end{aligned}$$
